AUTHOR: Dzhaparidze, K.G.

TITLE: Investigation of the molecular structure of tetramethylene silane by electron diffraction

PERIODICAL: Akademia nauk Gruzinskoy SSR. Soobshcheniya, v. 29, no. 4, 1962, 401-404

TEXT: A number of electron diffraction patterns were obtained from vaporized tetramethylenesilane,  $\text{CH}_2(\text{CH}_2)\text{CH}_2\text{SiH}_2$ , to determine the 3-dimensional structure of this compound. The resulting radial distribution function curves showed three maxima corresponding to the interatomic distances for C-C(1.54 $\text{\AA}$ ) Si-C(1.86 $\text{\AA}$ ) and Si....C(2.63 $\text{\AA}$ ). To establish the spatial configuration, 3 models were constructed, containing: (1) all atoms in one plane, (2) all carbon atoms in one plane, and (3) 3 atoms of the methylene ring in one plane. The results obtained from model (3) were in best agreement with the experimental results. Two isomers may therefore exist,

which cannot be differentiated by the diffraction method. The valency angle of silicon ( $\angle \text{SiCC}$ ) is  $104^\circ$ , which differs from the normal tetrahedral angle of carbon; it therefore requires less energy to deform  $\angle \text{SiCC}$  than  $\angle \text{CCC}$ . There are 2 figures and 1 table.

TITLE: A proportional counter and shielding system for  
radiocarbon dating

PERIODICAL: Pribery i tekhnika eksperimenta, no.6, 1962, 52-54

TEXT: A new proportional counter is described. It has a working volume of 4.5 litres and can withstand pressures of 10-15 atm. It is illustrated in Fig.1, in which 7 is a copper cylinder 60 cm long (outer diameter 12.5 cm, wall thickness 0.5 cm). Copper was chosen on the basis of minimum radioactive contamination. The central wire is kept under tension by the copper piston 1 which lies inside a perspex insulator 2 which is 22 cm long and has a corrugated surface designed to minimise leakage currents. The anode is in the form of a tungsten wire surrounded by a guard ring 4. One end of the wire is taken out through the insulator 2 and the other is held in position by a spring 8 attached to a teflon holder which is supported by the porcelain tubes 6. This method of attachment ensures that high voltages up to 25 kV  
Card 1/3

A proportional counter and shielding... S/120/62/000/006/007/029  
E032/E114

can be applied and the tension in the wire can be conveniently regulated. The evacuation and filling of the counter are carried out through the valve 10. The working gas for the counter was prepared in a special installation in which the specimen under investigation was first burned in a stream of oxygen flowing through a stainless steel tube at a temperature about 500 °C. This was followed by chemical conversion and final drying of the resulting CO<sub>2</sub>. In order to reduce the background of the counter it was surrounded by a Geiger counter screen in anti-coincidence with the proportional counter. At a pressure of 2 atm the counting rate for contemporary carbon was found to be 68.4 p.p.m. at a background (under similar conditions) of 27.3 p.p.m. This should ensure dating measurements of up to 43 000 years (48 hour counting interval). There are 4 figures.

TITLE: Synthesis and certain photochemical properties of 7-nitro-1', 3', 3'-trimethyl-spiro-naphthopyran- 2,2'-indoline	
SOURCE: AN GruzSSR. Soobshcheniya, v. 40, no. 3, 1965, 607-612	
TOPIC TAGS: photoeffect, spiropyran compound, UV irradiation, spectrophotometry, cryogenic effect / 7-nitro-1', 3', 3'-trimethyl-spiro-naphthopyran- 2,2'-indoline	
ABSTRACT: On the assumption that the change in color on heating of 1', 2', 3'-trimethyl-indoline- $\beta$ -naphthopyrilo-spiran, a substance synthesized by Wizinger and Wenning in 1940 (Helv. Chem. Acta, v. 23, 1940, 247) is associated with the splitting of the pyran cycle and hence also with a change in internal configuration and redistribution of bonds in the molecule, and in view of the importance of this problem, the authors synthesized yet another representative of nonsymmetric spiropyranes, namely, 7-nitro-1', 3', 3'-trimethyl-spiro-naphthopyran- 2,2'-indoline (yellowish acicular crystals) through condensation of 8 g of Fisher's base with 8 g of 6-nitro-2-oxy- $\beta$ -naphthaldehyde (Fig. 1) by heating to 60°C for 1 hr, thus obtaining a thermo-

chromic compound which, in a ligroin solution, is colorless at room temperature but acquires a purple color when heated to 100-150°C. The photochromic properties of this new spironpyran were investigated in a specially designed cryostat (attachment to an SF-10 spectrophotometer). The investigation was performed in liquid (paraffin oil and a mixture of ethanol and methanol in the mutual ratio of 4:1) and solid (polystyrene-ethyl cellulose) solutions. Findings: ultraviolet irradiation at room temperature does not change the color of solution. A reduction in temperature to -10°C in the liquid solution, however, along with a subsequent brief irradiation with  $\lambda = 366 \text{ m}\mu$  causes the solution to acquire a purple color. A peak in the 580 m $\mu$  region appears in the absorption spectrum. The process is reversible with time. At still lower temperatures (-90 to -100°C), on the other hand, the process becomes irreversible so long as these temperatures apply. Increasing the temperature instantaneously restores the original pale-yellow color. Orig. art. has: 5 figures, 2 formulas.

"The Problem of Titrating Antiplague Serum With Specific Polysaccharide of Plague Pathogen," by M. N. Dzhaparidze and N. K. Sidorova, Institute of Microbiology and Epidemiology of the Southeastern USSR, Zhurnal Mikrobiologii, Epidemiologii i Immunobiologii, No 9, Sep 56, pp 78-81

This article describes a new method for determining the quality of antiplague serums by titration of the protective properties of the serum with a specific polysaccharide of the plague pathogen. A polysaccharide was obtained by Korobkova, Kuznetsova, Bakrakh, and Shalayeva. They studied its chemical composition and properties and proved its specificity.

For the titration of antiplague serum, a 0.1 N acetic acid hydrolysate of microbial cells (according to the method of Korobkova and others) was used to obtain specific polysaccharides from avirulent strains YeV and No 17, and from virulent plague strains No 814, 571, and 708. All these polysaccharides, which were found to have a nitrogen content of about 4.5%, gave negative tests with trichloroacetic and sulfasalicylic acids. It was established that preparations obtained from oceanic strains (YeV and 751) contained 17-18% reducing sugars before hydrolysis in HCl and 35-40% after hydrolysis, while polysaccharides from continental strains (No 17, 814, and 708) contained 7-10% and 22-24%. All the polysaccharide preparations gave positive ring precipitation reactions with antiplague serum. The effect of the temperatures at which pathogens were cultured on the specificity of polysaccharides obtained from them was investigated.

In ring precipitation tests performed with 36 antiplague serums and polysaccharides from strain YeV cultured at 37°C and 28°C, preparations almost identical in specificity were obtained. The effect the virulence of the initial strain and its relation to glycerin had on the results of titration was determined. Ten antiplague serums were titrated with polysaccharides from avirulent strains YeV and No 17 and with virulent strains No 708, 814, and 751. Results of titration with polysaccharides from strains YeV and 751 were similar; the titer of different serums was  $140 \times 10^3$ . Fractions of polysaccharides which reacted in low concentrations (from  $10^{-3}$  to  $5 \times 10^{-3}$ ) were obtained from continental strains independent of their virulence. No qualitative difference was noticed as a result of titration. The qualitatively identical relationship of the polysaccharides to the serums made it possible to use any of the strains tested.

Vaccine strain YeV, cultured at 37°C, was chosen as most suitable for mass preparation of polysaccharide. For titration, the ring precipitation test was performed with 0.3 ml of antiplague serum in a dilution of 1:5, and 0.3 ml of different dilutions of polysaccharide. The reaction was read after standing for 3 hours at 24-25°C.

Thirty-two antiplague serums prepared in 1955 were selected for the basic titration experiments. In addition to the determination of the ring precipitation reaction titer of the specific polysaccharides, the protective properties of all the serums were studied on male and female white mice. Within a day after the subcutaneous introduction of 0.3 ml of serum, the mice were infected with 10 Dcl (500 microbial bodies) of virulent strain No 814. Results were determined within 2-3 weeks after infection.

Inasmuch as the basic criterion of the quality of a serum was the determination of its protective effect on animals, further experiments along this line were performed. White mice were used in all the titration experiments. It was found that 80-100% of the female mice and 20-50% of the male mice were protected by the same serum; therefore only male white mice were used in subsequent experiments.

In a comparative study of the results obtained from titration of the protective properties of antiplague serums by biological methods and by the ring precipitation test with specific polysaccharide, it was shown that serums with a ring precipitation titer of 1:50,000 and lower protected animals from infection with 10 Dcl of plague pathogen on an average of 40%, and serums with a titer of 1:70,000 and higher, 72%. It was consequently established that a direct relationship existed between the prophylactic properties of antiplague serums and their relationship to a specific polysaccharide. Results of these experiments are given in a table.

The precipitation reaction with a polysaccharide was positive only with beta- and gamma-globulin fractions of antiplague serums. This reaction is therefore considered to be a sufficiently precise method for titration of the protective properties of antiplague serums, affording 90% correct evaluation of the quality of the serums. It was concluded that any avirulent or virulent strain of plague pathogen cultured at 37°C or 28°C could be used, and that polysaccharide preparations from them were stable and could be stored and standardized according to chemical indexes i.e., the percentage of reducing substances. The ring precipitation method is recommended as one method of determining the protective properties of antiplague serums or their globulin fractions.

"Ixodidae of the Georgian Steppes (Georgian, resume in Russian)", Tr. In-  
ta Zoologii AN Gruz. SSR, No 2, pp 73-86, 1953.

The Shiransk, Udabniysk, and Samgorsk steppes were investigated in a study of the Ixodidae of the Georgian steppes. The Shiransk steppe was chosen as the steppe most representative of Georgian conditions. Eleven species were collected: *Ixodes eldaricus* Dzar., *Hemaphysalis sulcata* Can. and Franz., *H. punctata* Can. and Fanz., *H. otophila* p. Sch., *H. numidiana* Neum., *Boophilus calcaratus* Bir., *Dermacentor marginatus* Sulz., *Rhipicephalus bursa* Can. and Fanz., *R. turanicus* B. Pom., *Hyalomma egyptium* L., and *H. plumbeum* (Panz.). Of these, the most typical inhabitants of the steppes which were investigated were *H. sulcata* Can. and Fanz., *H. otophila* P. Sch., *Rhipicephalus bursa* Can. and Fanz., *R. turanicus* B. Pom., and *Hyalomma egyptium* L. The epizootic importance of *H. sulcata*, *R. bursa*, *B. calcaratus*, and *H. plumbeum* was established, and measures for the use of acaricides were suggested.

Title : Tics. Ixodes of Lagodekhsk Govern. Preserve and the  
Biological Characteristics of its Main Representatives

Orig Pub : Tr. In-ta zool. AN GruzSSR, 1956, 14, 87-104

Abstract : While the Lagodekhsk territory served as pasture, there were found 15 kinds of tics. After pasturing was discontinued, four kinds of tics disappeared: Boophilus calcarus, Dermacentor marginatus, Hyalomma plumbeum and Rhipicephalus bursa. The dominant kind appears to be Ixodes ricinus, which is encountered here simultaneously in the lower, middle and higher belts of woods, rising up to 2200m, above sea level. Adult I. ricinus begin to appear early in March; their maximal activity is observed in April and October; in winter, no animals were found. Larvae and nymphs are most active between June and August.

P-3

Abs Jour : Referat Zhur - Biologii, No 16, 1957, 70165

In sated larvae and nymphs, we observed an arrested development up to 400 days. The next most frequent one is *I. redikorzevi*; it is most frequent in the lower stratum of woods, parasitic to rodents, birds and insects; the season of parasitic activity of all phases of development extends from early spring to deep fall. Way of life; burrowing. Cycle of development: 2-3 years. Most frequently found form, *Haemophysalis concinna*; the remaining, *Rh. turanicus*, *Rh. sanguineus*, *Rh. rossicus* J. *crenulatus* and *H. inermis* are found in insignificant quantities. *I. frontalis*, *I. laguri armeniacus* and *I. tagodechensis* are singular. As possible disease carriers of useful animals, *I. ricinus*, *Rh. turanicus* and *H. concinna* might be of practical significance in the preserve.

TITLE: A Chemical and Technological Investigation of the Carbonaceous Shales of Tkibuli with the Object of Production of Industrial and Household Gas Therefrom (Khimiko-tekhnologicheskoye issledovaniye tkibul'skikh uglistykh slantsev s tsel'yu ikh pererabotki na promyshlennyy i bytovoy gaz)

PERIODICAL: Tr. In-ta metalla i gorn. dela. AN GruzSSR, 1957, Vol 8, pp 193-216

ABSTRACT: A description is presented of an investigation of the gasification of Tkibuli carbonaceous shales of the following % composition: 4% effective moisture, 54.4% ash per dry shale, 58.2% volatiles in the combustibles, 32.18% C and 3.39% H per dry shale, and a heat value of 3242 kcal/kg. Low-temperature carbonization in a rotating retort at 540°C yields 83.71% semicoke, 4.66% tars, and 3.36% gas having a heat value of 7000 kcal/m<sup>3</sup>. In continuous gasification with a 4-t layer-type generator using steam-and-air blast, 1470 m<sup>3</sup>/t gas of 1225 kcal/m<sup>3</sup> was obtained. The gasification efficiency was 58%

Card 1/2

SOV/137-58-7-14105

A Chemical and Technological Investigation (cont.)

in cold gas, and 72% in gas and tar; 18% of the steam was decomposed. Gasification of the shales in a compartment furnace yielded  $290 \text{ m}^3/\text{t}$  of high-calorificity gas with a heat value of  $3900 \text{ kcal/m}^3$ , 40 kg/t of tar and 700 kg/t of coke of 25% C content, the heat value being 2000 kcal/kg. On gasification, 1 t of compartment-furnace coke yields  $1180 \text{ m}^3$  of gas of  $1000 \text{ kcal/m}^3$  heat value.

TITLE: Determination of the slip coefficient of vortices in rotating liquid helium II

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 50, no. 2, 1966, 323-326

TOPIC TAGS: liquid helium, quantum liquid, flow measurement, vortex tube

ABSTRACT: To eliminate the effect of slip on measurements of the tension of Onsager-Feynman vortex filaments in liquid helium, the authors have constructed an instrument in which the vortices are subjected to continuous action, so that they cannot resume their initial configuration during the observation time, and their stationary deformation can be determined. The instrument comprises a torsion

Card 1/3

L 23750-66  
ACC NR: AP6007210

pendulum (Fig. 1) which can be rotated together with the liquid helium by a permanent magnet coupled to a telechron motor. The interaction between the vortices and a solid disc rotating in the helium was determined by measuring the lag of the freely suspended disc relative to a suspension that rotates additionally relative to the disc. An optical system was used to record the relative displacements of the suspension and of the disc. The measured lag amounted to approximately  $(4.4 \pm 0.4) \times 10^{-3}$  radians at

TITLE: Decay of Onsager-Feynman vortices and collectivization of vortex oscillations

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 50, no. 2, 1966, 327-329

TOPIC TAGS: liquid helium, quantum liquid, vortex tube, rotation, vortex

ABSTRACT: The purpose of the investigation was to measure the half-life of the vortices produced in rotating helium II after the vessel stopped rotating. The measurement setup was the same as used in a companion paper by the authors in the same source (ZhETF v. 50, 323, 1960; Acc nr: AP6007210), and the measurement procedure consisted of rotating the liquid helium for more than 30 minutes to establish a stationary rotation mode, stopping the motor, and determining the half-life of the vortices by calculating from the difference of two

Card 1/2

L 23742-66

ACC NR: AP6007211

dampings, the damping of the disc in the stationary helium II, and the damping at a certain instant of time after stopping the container. Plots of the logarithm of the excess damping on the time, made at 1.46K, show that the damping curves consist of two straight lying sections with different slopes, corresponding to two time constants.

In the case of a velocity of  $0.24 \text{ sec}^{-1}$ , the decay had a lifetime of  $70 \pm 5$  seconds at times shorter than 140 seconds after the start of the deceleration of the liquid, and  $55 \pm 5$  seconds after 140 seconds.

In the case of  $0.48 \text{ sec}^{-1}$  angular velocity the change in the half-life occurred at 250 seconds. At low velocity ( $0.10 \text{ sec}^{-1}$ ), the decay only had a single half-life. The presence of two half-lives is attributed to collectivization of the vortices. The authors are grateful to Yu. G. Mamaladze for participating in the discussion of the results. Orig. art. has: 2 figures and 1 formula.

TITLE: Study of the character of oscillations of helium II near the surface of an oscillating disc by the resonance method

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 50, no. 4, 1966, 856-860

TOPIC TAGS: liquid helium, quantum liquid, vortex, superfluidity, *WAVE PROPAGATION*

ABSTRACT: The purpose of the investigation was to determine the depth of penetration of the supercritical (vortical) oscillations produced in He II in which a disc oscillates with amplitude above a critical value, and caused by formation of quantum vortex filaments. To determine the penetration and to study the character of the propagation of the waves generated by the disc in this region, the authors used a special setup permitting measurement of the oscillations by reflecting a beam of light from a suspended mirror. The tests show that at amplitudes below critical, the depth of penetration agrees with the value obtained for a viscous wave, but at supercritical amplitudes the depth of penetration decreases with increasing amplitude. In the subcritical mode, the depth was  $0.48 \pm 0.02$  mm, and in the supercritical mode the values obtained were  $0.33 \pm 0.01$ ,  $0.36 \pm 0.01$ , and  $0.40 \pm 0.01$  mm at amplitudes of 0.73, 0.61, and 0.44 radians, respectively. The temperature dependence of the depths of

Card 1/2

L 32612-66

ACC NR: AP6014023

penetration for subcritical and supercritical modes are determined in the range 1.6 - 1.9K, in order to determine the contribution made by the dragging of the superfluid component to the effective depth of penetration of the waves. Both depths decrease with increasing temperature in quantitative agreement with the theoretical deductions. An empirical formula is presented for the depth of penetration of the supercritical oscillations. The authors thank Yu. G. Mamaladze for a discussion of the results. Orig. art. has: 7 figures, 4 formulas, and 1 table.
